Abstract: The overall project schedule is the basement of construction project. Any problem in it will cause huge economic loses, and it must be checked before being implemented. This paper introduces real value into DSM (design structure matrix), proposes a new checking and sorting method, and designs detailed processes and rules. Additionally the effectiveness of the method is proved through applying it to an example.

Keywords: Project Schedule, Sorting, DSM, Topology.

1. INTRODUCTION

Building projects can be complex. They demand accurate project scheduling and task management to ensure they go to plan. Before the start of the project, the General Contracting Unit should prepare its overall project schedule which is implemented after it is approved by the supervision, the project company, and then the project management division, vice-president. The overall progress of the program should define measure, requirements and station time of each sub-unit, and provide a time reference. The General Contracting Unit must be liable for breach, if construction period delay is caused by the inaccurate overall schedule. So the overall schedule must be checked before being implemented.

First, the project Gantt chart, as shown in Fig. (1), should be developed in the project schedule progress. The basic requirement of the project: a project must begin after its pre-project having been completed. This means that the progress must be sorted and checked according to the requirement.

The project Gantt chart must be checked first because of plenty of projects and long duration. Detection method commonly used is to convert it into a AOE network, then the AOE is topologically sorted. [1, 2] Traditional topological sorting method first inputs AOE network, then finds a vertex which hasn't a direct precursor, outputs and deletes it, the process is repeat N(the number of vertices) times; if the process stops before N times, that means the project schedule is

wrong. There are 26 points in a simplified AOE as showed in Fig. (2), if it is right, the sorting repeat 26 times, otherwise, the schedule must be done again from beginning.

2. DSM SORTING METHOD

2.1. DSM

There has already been an excellent review by Browning in general areas of DSM application. They categorized DSM models into four types according to their characteristics and applications:

- 1) Component-Based DSM: which documents interactions among product components, can be used to facilitate appropriate modularization of a complex system;
- 2) Team-Based DSM, useful for depicting the interactions among design teams;
- 3) Activity-Based DSM, effective in modelling the information dependencies among design activities;
- 4) Parameter-Based DSM, for documenting physical design parameter relationships. Please read through the following sections for more information on preparing your paper. However, if you use the template you do not have to worry about setting margins, page size, and column size etc. as the template already has the correct dimensions.

Iteration, the repetition of design tasks, is a fundamental characteristic of design process. Iteration occurred in product development for two main reasons. First, tasks may need to be reworked when review or testing activities detect some faults in the original design. Second, when modified information is passed along from upstream, some of the downstream work may be obsolete and need be reworked.

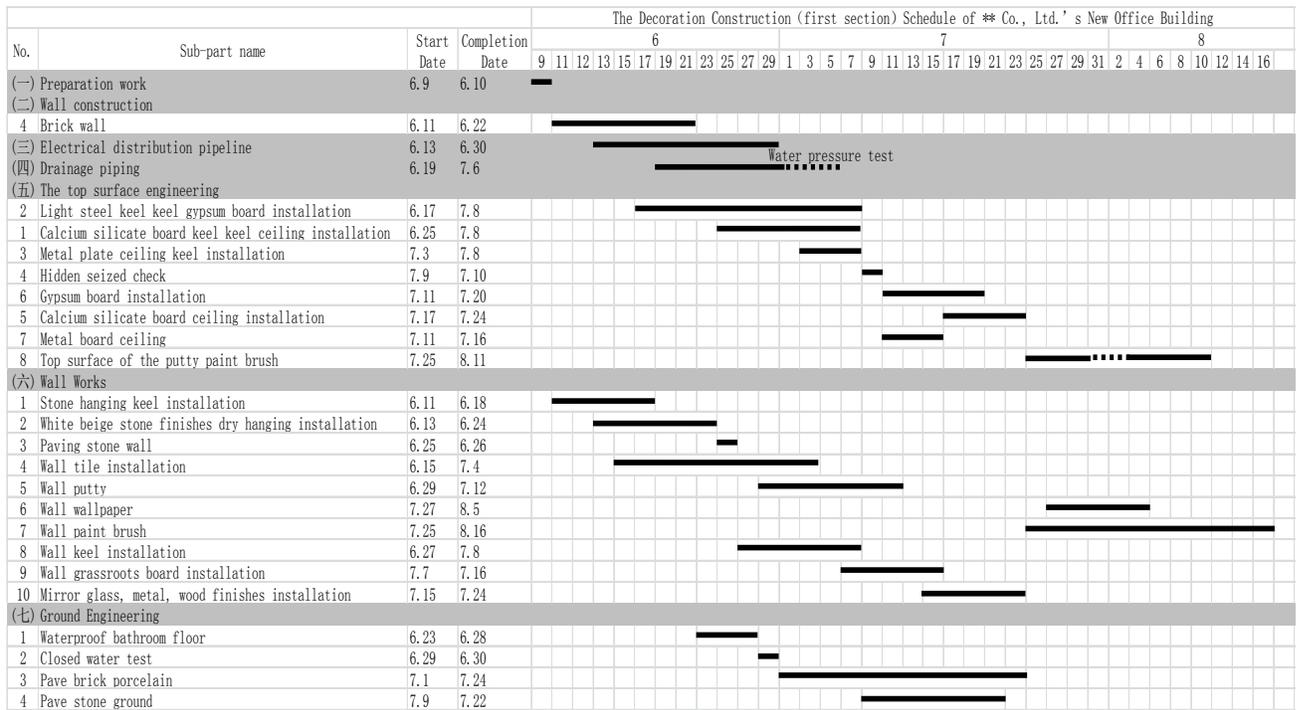

Fig. (1). The gantt chart of a project.

The iterative nature of product development can be addressed by using DSM. As shown in Fig. (2), the basic DSM is a binary matrix representation of a project with elements denoting individual design tasks and off diagonal marks representing the information dependencies among these tasks. Along each row, the off diagonal marks indicate all of the tasks whose output information is required to perform the task corresponding to that row. Reading down each column reveals that which other tasks receive its output. When activities are executed in the order listed from top to bottom, sub diagonal marks represent an input from upstream activities/stages to downstream activities/stages. Super diagonal marks denote a feedback from downstream activities to upstream activities. As such, the DSM approach provides a concise way in describing and investigating information transfer and iteration.

The principal concepts of DSM can be summarized as follow:

- 1) DPs of a system are intuitively elicited, often based on experience.
- 2) Dependencies between the DPs are represented in matrix form Fig. (3).
- 3) An 'X' in the matrix indicates a dependency between two DPs – the row-DP depends on the column-DP.
- 4) DP2 is concluded to be dependent on DP1, when DP1 is an input to DP2 – modifying DP1 affects DP2
- 5) Modular design (modularity) is achieved by clustering inter-dependent DPs, and by information hiding, to form modules.

6) Modules are units in a larger system that are structurally independent of one another, but work together [5, 6].

2.2. DSM Sorting Method

With development of research on Design Structure Matrix (DSM), DSM is widely used in construction, semiconductor, automation, photography, aviation, communications, small-scale manufacturing, assembly plant, e-business, project planning and control, product development, workflow, software development and other fields. Disadvantage of DSM is that the matrix elements are some vague values: Most use Boolean constant, the symbol "X", "●" and other information to indicate the interaction between activities. Later the matrix elements are modified by numbers, which only show the degree of dependence between activities, so that the application of DSM modelling and optimization is still qualitative, and unable to meet the Quantitative characteristics of the project processes [3-7].

This paper presents a method based on improved DSM: first it will reduce the complication of the network, and then improve efficiency of the algorithm, while also record the specific project which does not meet the requirement, targeted the wrong parts in the schedule.

The elements of DSM are modified by real value, and the process of the DSM sorting method is designed as follows:

Step 1. Input AOE and establish DSM matrix A according to equation (1).

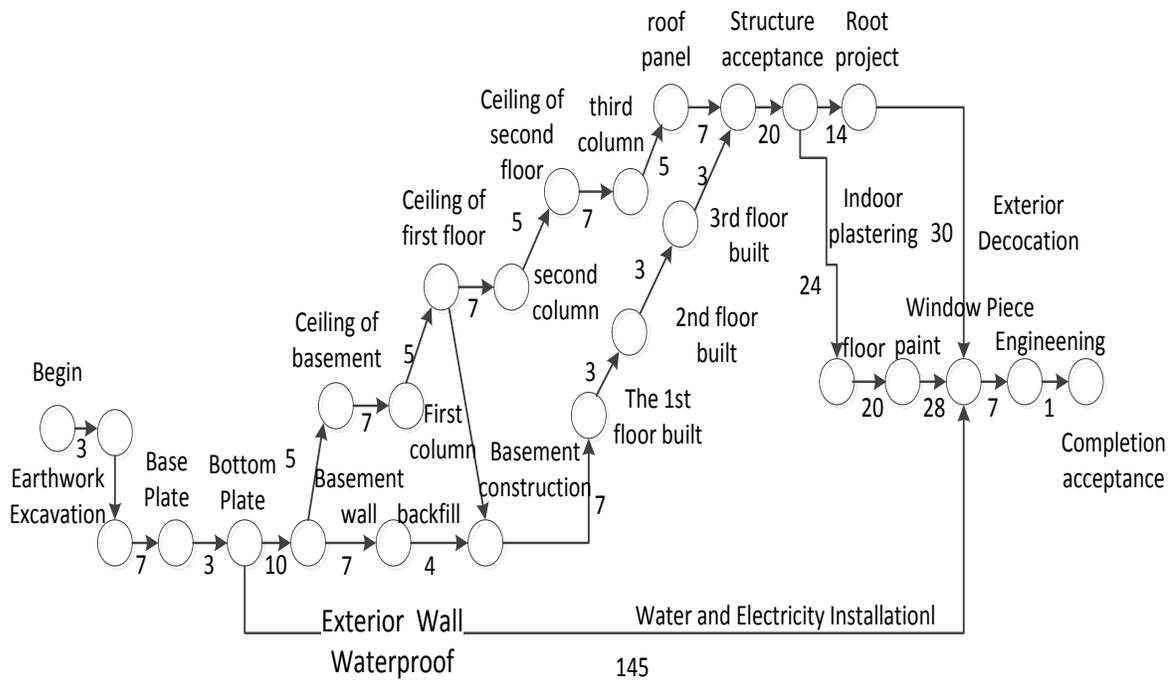

Fig. (2). AOE simplified from a gantt chart.

Activities		1	2	3	4	5	6	7
Architecture Layout	1	■						
Industrious Design	2	x	■	x				
Mechanical Design	3	x	x	■	x			
PCB layout	4	x		x	■			
Software Design	5	x				■		
Prototyping	6		x	x	x	x	■	
Testing	7					x		■

Fig. (3). Example of design structure matrix.

$$A = [a_{ij}]_{n \times n}, a_{ij} = \begin{cases} W(i, j), & \text{if } i \neq j \text{ and } i \text{ is adjacent to } j; \\ 0, & \text{else.} \end{cases} \quad (1)$$

Step 2. Cluster or combine activities. If one point have only one pre-activity and one post-activity, they can be merged as one activity, the value of it is pre-activity's plus post-activity's ($a_{ij} = a_{ij} + a_{jk}$). This step is always done with Step 3 together.

Step 3. Adjust the order of activities. In A, nonzero element in the row display the flow of information required to carry out the activity, and in the column indicates that the output flow of the activity. If all the elements of a row on A are zero, the activity responding to this row should be

executed as early as possible, because it is the source point of the whole activity process and does not need any information of other activities. We adjust it on the first row and column on A, and mark the activities (which need information flow of this point) as candidate sources.

If all the elements of a column are zero, the activity responding to this column should be executed behind other activities, because it is the terminal point and provides no information to the others. We put it on the last column and row on A and mark the activities (which flow information in this point) as candidate meeting point.

Step 4. In a similar way, we can adjust other activities on A in turn.

CONCLUSION

The overall project schedule is the basement of a construction project, but it goes wrong sometimes because of large number of projects in it. So the schedule must be checked before being implemented. In this paper, real values were introduced into DSM, and a new topological method was proposed. At last, the example showed that the method could reduce the number of activities and shorten the time, so it is more effective compared to the traditional method.
